CONTENTS

LAPLACE TRANSFORMS

First Lecture

Textbook: Gardner and Barnes, "Transients in Linear Systems"
Wiley, 1942

Other books by Berg, Bush, Cohen, Carson, Kurtz and Corcoran, Skilling, Stephens, and Churchill may be consulted.

Aim of course: to provide a technique for solving practical transient problems.

The classical method will be studied first, using as an example a series-peaked video amplifier stage. This problem will later be solved operationally. We assume a "unit step" current applied to the interstage coupling circuit, defined by:

$$i = 0 \quad , \quad t < 0$$

$$i = i_0 \quad , \quad t > 0$$

The circuit and terminology are as shown below:
The problem will be solved when we have found e (t). The standard classical procedure would be to set up a differential equation in which e (t) is the unknown and i (t) the driving function. However, even in this relatively simple problem, the driving function is not differentiable, and the procedure described would fail.

Hence, even in this case we must use an artifice in order to arrive at e (t), which consists of finding i2 (t) first, and then using the solution of the sub-problem to find e (t). The fundamental equations of the circuit may be written as follows:

$$i_1 = i - i_2 = C \frac{de}{dt} \tag{1}$$

$$R i_2 + L \frac{di_2}{dt} = e(t) \tag{2}$$

In order to eliminate i, we differentiate (2):

$$\frac{de}{dt} = L \frac{d^2 i_2}{dt^2} + R \frac{di_2}{dt} = \frac{1}{C}(i - i_2)$$

Rearranging this equation, we have for the differential equation giving i2:

$$\frac{d^2 i_2}{dt^2} + \frac{R}{L} \frac{di_2}{dt} + \frac{i_2}{LC} = \frac{i(t)}{LC} \tag{3}$$

This may be put into a standard form by substituting

$$2a = \frac{R}{L} , \qquad \ell^2 = \frac{1}{LC} \tag{4}$$

The differential equation is then

$$\frac{d^2 i_2}{dt^2} + 2a \frac{di_2}{dt} + \ell^2 i_2 = \frac{i(t)}{LC} \tag{5}$$

The solution of which is:

$$i_2 = C_1 e^{-(a + \sqrt{a^2 - \ell^2})t} + C_2 e^{-(a - \sqrt{a^2 - \ell^2})t} \tag{6}$$

It is seen that the condition for oscillations is:

$$\ell^2 > a^2, \quad \text{or} \quad \frac{1}{LC} > \frac{R^2}{4L^2}, \quad \text{or} \quad Q > \frac{1}{2}, \quad \text{where} \quad Q \equiv \frac{1}{R}\sqrt{\frac{L}{C}}.$$

The constants C_1 and C_2 may be evaluated from the initial conditions:

$$i_2 = 0 , \qquad \frac{di_2}{dt} = 0 \qquad \text{at} \quad t = 0 \tag{7}$$

We have then:

$$C_1 + C_2 + i_0 = 0 \tag{8}$$

$$C_1(a + \sqrt{a^2 - l^2}) + C_2(a - \sqrt{a^2 - l^2}) = 0$$

from which we have:

$$C_1 = \frac{i_0}{2}\left[\frac{a}{\sqrt{a^2 - l^2}} - 1\right]$$

$$C_2 = -\frac{i_0}{2}\left[\frac{a}{\sqrt{a^2 - l^2}} + 1\right] \tag{9}$$

The voltage e (t) may then be found from i_2:

$$e(t) = Ri_2 + L\frac{di_2}{dt} = R\frac{i_0}{2}\left[\left(\frac{a}{\beta} - 1\right)e^{-(a+\beta)t} - \left(\frac{a}{\beta} + 1\right)e^{-(a-\beta)t}\right]$$

$$+ L\frac{i_0}{2}\left[-\frac{l^2}{\beta}e^{-(a+\beta)t} + \frac{l^2}{\beta}e^{-(a-\beta)t}\right]$$

Combining terms, we have:

$$e(t) = Ri_0\left[1 - \frac{1}{4}\left(2 - \frac{a}{\beta} - \frac{\beta}{a}\right)e^{-(a+\beta)t}\right.$$

$$\left. - \frac{1}{4}\left(2 + \frac{a}{\beta} + \frac{\beta}{a}\right)e^{-(a-\beta)t}\right] \tag{10}$$

where

$$\beta \equiv \sqrt{a^2 - l^2} = \sqrt{\frac{R^2}{4L^2} - \frac{1}{LC}} = \omega_0\sqrt{\left(\frac{1}{2Q}\right)^2 - 1} \;.$$

This is the solution of the problem. There are a few general-
izations that may be made about the classical method. It is found
that in all networks in which the components are linear and inde-
pendent of time, the differential equations are of the type known
as linear equations with constant coefficients. Their solution
consists of the complementary function, which is the general solution
of the homogeneous differential equation obtained by putting the
driving-force equal to zero, and a particular integral which depends
on the form of the driving-force function. These are known to the
engineer as the transient and steady-state responses respectively.

The transient part of the solution contains a sufficient number of
arbitrary constants to enable it to meet all the prescribed initial
conditions. The functions appearing in the transient are always
exponential. If these exponentials are complex they always occur
in complex conjugate pairs, so that their sum represents a real,
exponentially damped oscillation. The difference between two
real exponential functions occurs often and is called a <u>surge</u> function
It has the form illustrated below:

$$f(t) = e^{-at} - e^{-\ell t}$$
The two modes for a simple LRC circuit vary with increasing losses
as shown below:
With no losses, ($Q = \infty$) the modes are at $\pm j\omega_o$, and re-
present an undamped sine wave, since $e^{j\omega_o t} + e^{-j\omega_o t} = 2\cos\omega_o t$.
As losses increase, the modes move along the arc of a circle, re-
presenting an exponentially decaying oscillation of lower frequency
than ω_o . Critical damping occurs when the modes coincide at
$Q = \dfrac{\omega_o L}{R} = \dfrac{1}{R}\sqrt{\dfrac{L}{C}} = \dfrac{1}{2}$, and at this point there is only a single ex-
ponential term $e^{-\omega_o t}$. As the losses increase further, the modes

separate, and move along the real axis, where at infinite loss one

approaches ($\pm \infty$) and the other approaches zero.

The distinction between transient and steady-state is very

great in the classical method of solution, but it is a mathematical

rather than physical distinction, which is lost in the operational

method of. solution.
The Heaviside Operational Method

In the Heaviside method, we obtain an operational equation from

the differential equation by substituting $p = \dfrac{d}{dt}$, $p^2 = \dfrac{d^2}{dt^2}$, $\dfrac{1}{p} = \displaystyle\int_{0-}^{t}(\ )dt$,

$\dfrac{1}{p^2} = \displaystyle\int_{0-}^{t}\int_{0-}^{t}(\ )dt^2$, etc.   . This transforms an

integro-differential equation into an algebraic one. If this is

solved for the unknown treating p as an algebraic quantity, the re-

sult is a symbolic solution involving p and the driving function.

This can be converted into a real time function if we know how to

interpret the operational equations; we will now consider how this

is done. The fundamental type of driving function is the unit step

which is defined by:

$$1 = \left\{ \begin{array}{cc} 0 & , \ t < 0 \\ 1 & , \ t > 0 \end{array} \right\}$$

Heaviside found, by working backwards from known solutions of simple

differential equations, that the following interpretations of

operational expressions could be made:

$$\frac{1}{p}1 = \int_{0-}^{t} dt = t\,1 \qquad , \qquad \frac{1}{p^2}1 = \int_{0-}^{t} t\,dt = \frac{t^2}{2}1$$

and, in general, we have:

$$\frac{1}{P^n} \mathbf{1} = \frac{t^n}{n!} \mathbf{1} \qquad (11)$$

It should be clearly understood what this type of equation means; it is not valid to cancel out the $\mathbf{1}$ sign, because the left hand side of the equation is not a product, but rather represents an operation on $\mathbf{1}$. The right hand side, however, is an ordinary product, and simply means that the time function is cut off before t equals 0, which amounts to assuming zero for all initial conditions. We see that if some function $F(P)$ is given, the result of operating with this function on the unit step $\mathbf{1}$ may be found by expanding F (P) in a power series in $\frac{1}{P}$, after which each term may be interpreted according to equation (11). Heaviside called this process "algebrizing". By means of it, an answer in the form of a power series in t can be obtained for any F (P) that is analytic in $\frac{1}{P}$. Some of these power series are recognized as well-known functions; in this way the following identities have been established:

$$\frac{1}{P^n}\mathbf{1} = \frac{t^n}{n!}\mathbf{1} \qquad\qquad \frac{aP}{P^2+a^2}\mathbf{1} = \sin at\, \mathbf{1}$$

$$\frac{P}{P+a}\mathbf{1} = e^{-at}\mathbf{1} \qquad\qquad \frac{P}{\sqrt{P^2+a^2}}\mathbf{1} = J_o(at)\,\mathbf{1} \qquad (12)$$

We see that a time function can also be obtained in the form of a series of exponential terms if we expand F (P) into partial fractions of the form $\frac{kP}{P+a}$ and use the appropriate formula above. The general rule for this process is called the Heaviside expansion theorem. If F (P) is expressible as the ratio $N(P)/D(P)$ of two rational algebraic polynomials, we have:

$$\frac{N(P)}{D(P)} 1 = \frac{N(0)}{D(0)} + \sum_{K=1}^{n} \frac{N(P_K)}{P_K \, D'(P_K)} e^{P_K t} 1 \qquad (13)$$

where the P_K are the n roots of the equation $D(P) = 0$, and $D'(P_K)$ is the derivative $\frac{d D(P)}{d P}$ evaluated at $P = P_K$. It is seen that the different "modes" of network response appear as different solutions of $D(P) = 0$, which ensures that all complex roots will appear in complex conjugate pairs.

If the time function operated on by F (P) is not the unit step, it is usually easiest to express that time function in terms of a function G (P) operating on the unit step, so that the product F (P) G (P) then becomes the function to interpret. For example,

$$\frac{1}{P+a} \left(\sin Lt \; 1 \right) = \frac{1}{P+a} \left(\frac{L}{P+L} 1 \right) = \frac{L}{(P+a)(P+L)} 1 = \frac{e^{-at} - e^{-Lt}}{L-a} 1 , \qquad (14)$$

Second Lecture

The last lecture covered classical and Heaviside methods of solving differential equations.

The reason for success of Heaviside method was that it reduced the differential equation to an algebraic one which could be solved easily. This was because we put $p = \frac{d}{dt}$ and $\frac{1}{p} = \int_{0_-}^{t} (\ ) dt$. All this was formalism, and its justification depended upon the possibility of interpreting the result of the algebraic solution, which interpretation could usually, but not always be made.

There is, however, another method of solution which has the same property of reducing the differential equation to an algebraic one, in a very similar way. The Laplace transform is defined by:

$$\mathcal{L}\left[F(t)\right] = \int_0^\infty F(t) e^{-st} dt = F(s) \tag{1}$$

It defines a functional transformation, and relates a time function $F(t)$ to a function of the complex variable S which for the moment has no physical significance. Examples are:

$$\mathcal{L}(1) = \int_0^\infty e^{-st} dt = -\frac{1}{s} e^{-st} \Big|_0^\infty = \frac{1}{s} \tag{2}$$

$$\mathcal{L}(t) = \int_0^\infty t e^{-st} dt = \frac{1}{s^2} \quad (\text{Integrate by parts}) \tag{3}$$

In general,	Compare Heaviside formulae:
$\frac{1}{s^{n+1}} = \mathcal{L}\left(\frac{t^n}{n!}\right)$	$\frac{1}{p^n} \, 1 = \frac{t^n}{n!}$
$\frac{1}{s+a} = \mathcal{L}\left(e^{-at}\right)$	$\frac{p}{p+a} \, 1 = e^{-at}$
$\frac{a}{s^2+a^2} = \mathcal{L}\left(\sin at\right)$	$\frac{ap}{p^2+a^2} \, 1 = \sin at$
$\frac{1}{\sqrt{s^2+a^2}} = \mathcal{L}\left[J_0(at)\right]$	$\frac{p}{\sqrt{p^2+a^2}} \, 1 = J_0(at)$

(4)

Notice the great similarity - there is one more power of P
than of S in each case. This is true in general, and is in fact
the relation by means of which mathematicians have been able to just-
ify the Heaviside rules for the solution of differential equations.
The operations of differentiation and integration are analyzed as
follows:

(Integrate by parts)

$$u = e^{-st}$$
$$du = -se^{-st}dt$$
$$dv = dF(t)$$
$$v = F(t)$$

$$\mathcal{L}\left[F'(t)\right] = \int_0^\infty \frac{dF(t)}{dt} e^{-st} dt$$

$$= F(t)e^{-st}\Big|_0^\infty + \int_0^\infty F(t)s e^{-st} dt$$

$$= -F(0) + s\int_0^\infty F(t)e^{-st}dt$$

$$= S F(s) - F(0) \qquad \left(\text{If } F(t) \text{ is continuous}\right) \qquad (6)$$

$$\mathcal{L}\left[\int_0^t F(t)dt\right] = \mathcal{L}\left[F^{(-1)}(t)\right] = \frac{1}{s}\left[F(s) + F^{(-1)}(0)\right] \qquad (7)$$

The initial conditions ~~were~~ are introduced automatically. It
is seen that the correspondence with the Heaviside method is kept
here, differentiation corresponding to multiplication of the time
function by P in the Heaviside system, and to multiplication of
the complex function by S in the Laplace method.

The reduction of the differential equation to an algebraic

one is then done as follows:

$$L \frac{di}{dt} + R i + \frac{1}{C} \int i \, dt = e(t) \tag{8}$$

Taking the $\mathcal{L}$ transform of both sides, we have:

$$\mathcal{L} \left[L \frac{di}{dt} + R i + \frac{1}{C} \int i \, dt \right] = \mathcal{L} \left[e(t) \right] = E(s) \tag{9}$$

Or, since the $\mathcal{L}$ transform is linear:

$$L \mathcal{L} \int \frac{di}{dt} + R \mathcal{L} \int i(t) + \frac{1}{C} \mathcal{L} \left[\int i \, dt \right] = E(s) \tag{10}$$

Using our formulas (6) and (7), we have:

$$L \left[s I(s) - i_0 \right] + R I(s) + \frac{1}{Cs} \left[I(s) + g_0 \right] = E(s) \tag{11}$$

This is now reduced to an algebraic equation in S. Note that
the initial conditions give the correct quantities to specify,
namely the initial current in an L, and the initial charge on a
C. Quantities such as the initial voltage on L are not per-
missible initial conditions, because they can be changed instan-
taneously. The Heaviside method automatically assumes zero initial
conditions, because the operational interpretation of $\frac{1}{P} = \int_{o-}^{t} (\quad) \mu t$
requires the (-0) as the lower limit, in order that P and 1/P be
exactly inverse operations, whereas the Laplace transforms have
($+$0) as the lower limit.

If we solve (11) for I (S), we have:

$$I(s) = \frac{E(s) + L i_0 - \frac{g_0}{Cs}}{Ls + R + \frac{1}{Cs}} \tag{12}$$

The denominator of (12) looks very much like the standard
expression for the steady-state impedance, if we replace S by $j \omega$.
It can be shown that this is true in general; in other words:

The relation between the transforms I (S) and E(S) is

identical with the relation between the A.C. vectors I and E for
the steady-state case, if ~~S and j w are equivalent.~~ $j\omega$ is replaced by S.

This rule is of great convenience, and enables us to by-
pass the differential equation stage unless there is some
difficulty with the initial conditions. If initial conditions
are ignored, the solution assumes them to be zero.

Third Lecture

We may apply this rule to the series-peaked video amplifier circuit discussed in lecture one, as follows:

$$E(s) = \frac{I(s)\left[(R+Ls)\frac{1}{Cs}\right]}{R+Ls+\frac{1}{Cs}} = \frac{I(s)\left[R+Ls\right]}{1+RCs+LCs^2} \tag{1}$$

The current applied was a unit step of amplitude i_0, so $I(s) = \frac{i_0}{s}$, and:

$$E(s) = \frac{i_0(R+Ls)}{s(1+RCs+LCs^2)} \tag{2}$$

Consulting the Gardner & Barnes tables, we find pair 1.109 to be closest, but it requires factoring the denominator of the equation:

$$E(s) = \frac{i_0}{C}\frac{\left(s+\frac{R}{L}\right)}{s\left(s^2+\frac{R}{L}s+\frac{1}{LC}\right)} \tag{3}$$

This requires solving the following equation for S:

$$s^2 + \frac{R}{L}s + \frac{1}{LC} = 0$$

The quadratic formula is used, $\left(\frac{-b \pm \sqrt{b^2-4ac}}{2a}\right)$.

The roots are then:

$$-\frac{R}{2L} \pm \sqrt{\frac{R^2}{4L^2} - \frac{1}{LC}} \tag{4}$$

We then can identify:

$$a_0 = \frac{R}{L}$$

$$\alpha = \frac{R}{2L} + \sqrt{\frac{R^2}{4L^2} - \frac{1}{LC}} = \frac{R}{2L} + \rho$$

$$\gamma = \frac{R}{2L} - \sqrt{\frac{R^2}{4L^2} - \frac{1}{LC}} = R/2L - \rho \tag{5}$$

The solution is then:

$$e(t) = \frac{i_0}{C}\left[\frac{a_0}{\alpha\gamma} + \frac{a_0-\alpha}{\alpha(\alpha-\gamma)}e^{-\alpha t} + \frac{a_0-\gamma}{\gamma(\gamma-\alpha)}e^{-\gamma t}\right] \tag{6}$$

$$= \frac{i_0}{C}\left[\frac{\left(\frac{R}{L}\right)}{\left(\frac{1}{LC}\right)} + \frac{\frac{R}{L}-\frac{R}{2L}-\rho}{2\rho\left(\frac{R}{2L}+\rho\right)}e^{-\left(\frac{R}{2L}+\rho\right)t} + \frac{\frac{R}{L}-\frac{R}{2L}+\rho}{(-2\rho)\left(\frac{R}{2L}-\rho\right)}e^{-\left(\frac{R}{2L}-\rho\right)t}\right]$$

This reduces to:

$$e(t) = Ri_0\left[1 + \frac{1}{2}\left(\frac{R}{2L\rho} - \frac{1}{\rho RC} - 1\right)e^{-\left(\frac{R}{2L} + \rho\right)t}\right.$$

$$\left. - \frac{1}{2}\left(\frac{R}{2L\rho} - \frac{1}{\rho RC} + 1\right)e^{-\left(\frac{R}{2L} - \rho\right)t}\right] \tag{7}$$

This may be rearranged in the more symmetrical form:

$$e(t) = Ri_0\left[1 - \frac{1}{4}\left(2 - \frac{R}{2L\rho} - \frac{2L\rho}{R}\right)e^{-\left(\frac{R}{2L} + \rho\right)t}\right.$$

$$\left. - \frac{1}{4}\left(2 + \frac{R}{2L\rho} + \frac{2L\rho}{R}\right)e^{-\left(\frac{R}{2L} - \rho\right)t}\right] \tag{8}$$

which agrees with the result arrived at in the classical method in lecture one.

Fourth Lecture

Correspondence between Laplace and Fourier transforms may be seen by writing:

$$F(s) = \int_o^\infty f(t)\, e^{-st}\, dt \quad , \qquad f(t) = \frac{1}{2\pi j} \int_{c-j\infty}^{c+j\infty} F(s)\, e^{st}\, ds \qquad (1)$$

then put

$$s = \sigma + j\omega, \qquad \sigma = o$$

$$F(s) = F(j\omega) = \int_o^\infty f(t)\, e^{-j\omega t}\, dt = \int_{-\infty}^\infty f(t)\, u(t)\, e^{-j\omega t}\, dt \qquad (2)$$

$$f(t) = \frac{1}{2\pi j} \int_{c-j\infty}^{c+j\infty} F(j\omega)\, e^{j\omega t}\, d(j\omega) = \frac{1}{2\pi} \int_{-\infty}^\infty F(j\omega)\, e^{j\omega t}\, d\omega \qquad (3)$$

The last formulae are called Fourier transforms. The extension of the lower limit to $(-\infty)$ in the direct transform is made easily if $f(t) = o, \ t < 0$. This is the main difference between the Fourier and Laplace transforms, and we will investigate further to see just how the complex inversion formula leads to time functions vanishing before $t = o$.

As a tool useful for later work, let us derive a preliminary result. Consider the function

$$\frac{\sin \omega t}{t} = \omega\, \frac{\sin(\omega t)}{(\omega t)}$$

as ω increases without limit:
The central peak becomes higher and sharper, and the "cycles"

crowd together as ω increases. However, the area under the curve remains finite and independent of ω, since:

$$\int_{-\infty}^{\infty} \frac{\sin \omega t}{t} \, dt = \pi \tag{4}$$

Now if this function is multiplied by a function $f(t)$ and integrated, the rapidly alternating plus and minus values of $(\sin \omega t)/t$ will cancel out contributions except in the neighborhood of t equals 0, where one infinite loop is not cancelled out by another one. This means that it is only values of $f(t)$ near to t equals 0 that can contribute appreciably to the integral. In the limit, the integral is given simply by the value of $f(0)$ multiplied by the area under the oscillating curve, which is π:

$$\lim_{\omega \to \infty} \int_{-\infty}^{\infty} f(t) \frac{\sin(\omega t)}{t} \, dt = \pi f(0) \tag{5}$$

Generalizing slightly by shifting the origin of the oscillating curve, we have a formula :

$$\lim_{\omega \to \infty} \frac{1}{\pi} \int_{-\infty}^{\infty} f(t) \frac{\sin \omega(t-u)}{(t-u)} \, dt = f(u) \tag{6}$$

or, interchanging the variables t and u : $\lim_{\omega \to \infty} \frac{1}{\pi} \int_{-\infty}^{\infty} f(u) \frac{\sin \omega(t-u)}{(t-u)} \, du = f(t) \tag{6a}$

Now we return to the Laplace formulae:

$$F(s) = \int_0^{\infty} f(t) e^{-st} \, dt = \int_0^{\infty} f(u) e^{-su} \, du \qquad \text{(since the variable of integration can be any symbol)} \tag{7}$$

$$f(t) = \frac{1}{2\pi j} \int_{c-j\infty}^{c+j\infty} F(s) e^{st} \, ds = \lim_{\omega \to \infty} \frac{1}{2\pi j} \int_{c-j\omega}^{c+j\omega} F(s) e^{st} \, ds \tag{8}$$

If we substitute (7) into (8), we have:

$$F(t) = \lim_{\omega \to \infty} \frac{1}{2\pi j} \int_{c-j\omega}^{c+j\omega} e^{st} ds \int_{0}^{\infty} F(u) e^{su} du \qquad (9)$$

The order of integration may be reversed, giving:

$$F(t) = \lim_{\omega \to \infty} \frac{1}{2\pi j} \int_{0}^{\infty} F(u) du \int_{c-j\omega}^{c+j\omega} e^{s(t-u)} ds \qquad (10)$$

Evaluating the inner integral, we have:

$$\int_{c-j\omega}^{c+j\omega} e^{s(t-u)} ds = \frac{e^{s(t-u)}}{(t-u)} \Bigg|_{c-j\omega}^{c+j\omega} = \frac{1}{(t-u)} e^{c(t-u)} \left[e^{j\omega(t-u)} - e^{-j\omega(t-u)} \right.$$

$$= 2j \, e^{c(t-u)} \frac{\sin \omega(t-u)}{(t-u)} \qquad (11)$$

We then have:

$$F(t) = \lim_{\omega \to \infty} \frac{1}{\pi} \int_{0}^{\infty} F(u) e^{c(t-u)} \frac{\sin \omega(t-u)}{(t-u)} du \qquad (12)$$

This is seen to be the same as (6a) except for the limits of integration. From the discussion preceding (6a) it is clear that negative values of t must lead to the value $F(t)$ equals 0, since contributions to the integral arise only when t and u "cross over". It is seen that the extra "converging power" of the Laplace transform due to the factor $e^{-\sigma t}$ is obtained at the expense of cutting off all time functions before t equals 0. If we wish to keep $F(t)$ for all values of time, we cannot use the term $e^{-\sigma t}$, but must put S equals $j\omega$, as in equations (2) and (3), which are standard Fourier transforms. In general, whatever lower limit was taken in the integral defining the direct transformation is the time before which the inversion integral gives $F(t)$ equals 0.
We may also see the above result from the theory of residues.

The Cauchy residue theorem is:

$$Res(a) \equiv \frac{1}{2\pi j} \oint \frac{F(z)}{z-a} dz = F(a) \qquad (13)$$

where the integral encloses the point $z = a$, and $F(z)$ has no

pole at $z = a$. The loop integral around any region is then

equal to $2\pi j \cdot \sum$ residues of all poles enclosed in the region.

For $t > 0$, we can define a loop enclosing all poles of the

function F (S) as below:

As the integral around the semi-circle vanishes for $R \to \infty$, the integral along the straight line is equal to $2\pi j \cdot \sum Res$. For $t < 0$, the factor e^{st} becomes divergent on the semicircle, and we have to complete the loop by a semicircle to the right of the straight line path. Since the new loop encloses no poles, we have

$$f(t) = 0 \quad for \quad t < 0.$$

Fifth Lecture

Development of Fourier Integral from Fourier Series

The usual form of a Fourier series is:

$$f(t) = \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos n\omega_0 t + \sum_{n=1}^{\infty} b_n \sin n\omega_0 t \tag{14}$$

where

$$a_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(t) \cos n\omega_0 t \; d(\omega_0 t) \quad , \quad b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(t) \sin n\omega_0 t \; d(\omega_0 t) \tag{15}$$

This can be put into the complex form by noting that the **sine** and cosine terms of any frequency may be combined as follows:

$$a_n \cos n\omega_0 t + b_n \sin n\omega_0 t = C_n e^{jn\omega_0 t} + C_{-n} e^{-jn\omega_0 t} \tag{16}$$

where

$$C_n = \frac{1}{2}(a_n - jb_n)$$

$$C_{-n} = \frac{1}{2}(a_n + jb_n) = C_n^{*} \tag{17}$$

$$C_0 = \frac{1}{2} a_0$$

We then have:

$$f(t) = \sum_{n=-\infty}^{\infty} C_n e^{jn\omega_0 t} \tag{18}$$

$$C_n = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(t) e^{-jn\omega_0 t} \; d(\omega_0 t)$$

The similarity between these and the Fourier transform formulae is evident. We will not go through the limit process because it is too difficult, but it can be seen that a change of variable results in the formula

$$C_n = \frac{\omega_0}{2\pi} \int_{-\frac{\pi}{\omega_0}}^{\frac{\pi}{\omega_0}} F(t)\, e^{-jn\omega_0 t}\, dt .$$

If now we let $\omega_0 \to 0$, the limits on variation of t increase without limit, and we become interested in much larger values of n, such that the product $n\omega_0$ remains finite, and equal to ω. Then we put $C_n = \frac{\omega_0}{2\pi} F(n\omega_0) = \frac{\omega_0}{2\pi} F(\omega)$, and we have:

$$F(\omega) = \int_{-\infty}^{\infty} f(t)\, e^{-j\omega t}\, dt \tag{20}$$
The other formula becomes:

$$f(t) = \sum_{n=-\infty}^{\infty} \frac{\omega_0}{2\pi} F(n\omega_0)\, e^{jn\omega_0 t} \tag{21}$$

This suggests the definition of an integral, which becomes, in the limit of $\omega_0 \to d\omega \to 0$:

$$f(t) = \frac{1}{2\pi} \int_{-\infty}^{\infty} F(\omega)\, e^{j\omega t}\, d\omega \tag{22}$$

so that both of the Fourier integral formulae can be deduced from the Fourier series formulae.

The ~~physical~~ *geometrical)* interpretation of a Fourier series is that of rotating vectors of various frequencies:

as $\omega_0 \to 0$, this merges into a continuous curve, the projection of the end of which is the voltage.

In general, Laplace transforms will solve definite problems with known initial conditions more easily, while the Fourier transform is best for general arguments about phase and amplitudes, since they are directly measurable.

Sixth Lecture

There are certain general conclusions that can be drawn from the Fourier analysis that are useful in a number of practical cases. For instance, if $f(t)$ and $F(\omega)$ are transforms of each other, we find that $f(t-t_o)$ and $F(\omega) e^{-j\omega t_o}$ are also transforms, so that an addition of a linear phase term corresponds to a time delay of one second for every cycle / cycle, ~~rate of phase change~~ slope of the phase curve. Similarly, $f(t) e^{\pm j\omega_o \tau}$ and $F(\omega \mp \omega_o)$ are transforms. The time function represents a carrier of frequency ω_o, ~~modulated~~ amplitude-modulated by $f(t)$, and the $F(\omega \mp \omega_o)$ term shows that the spectrum is simply that of $f(t)$ but centered around ω_o instead of zero.

If $f(t)$ or $F(\omega)$ is:	Real	Imaginary
Even	the other is: Real, Even	Imaginary, Even
Odd	Imaginary, Odd	~~Imaginary~~ Real, Odd

Using these theorems, we can find the effect of suddenly impressing a sine wave of frequency ω_o on a filter which passes frequencies from $\omega 1$ to $\omega 2$. The impressed ~~face~~ force is represented as $Re\left[u(t) e^{j\omega_o t}\right]$. The transform of the bracket is:

$$F(\omega) = \frac{1}{j(\omega - \omega_o)} \tag{1}$$

The network function is given by:

$$H(\omega) = 0, \ |\omega| < \omega_1$$
$$= 1, \ \omega_1 \leq |\omega| \leq \omega_2 \tag{2}$$
$$= 0, \ |\omega| > \omega_2$$

(No phase shift need be considered, as it would merely lead to a time

The response is then:

$$f_1(t) = Re \, \frac{1}{2\pi} \int_{-\infty}^{\infty} F(\omega) H(\omega) \, e^{j\omega t} d\omega$$

$$= Re \, \frac{1}{2\pi j} \int_{-\omega_2}^{-\omega_1} \frac{e^{j\omega t}}{(\omega - \omega_0)} \, d\omega \;+\; Re \, \frac{1}{2\pi j} \int_{\omega_1}^{\omega_2} \frac{e^{j\omega t}}{(\omega - \omega_0)} \, d\omega \qquad (3)$$

The integral over negative frequencies may be neglected if ω
is not too far from the positive pass band, so we have:

$$f_1(t) = Re \, \frac{1}{2\pi j} \int_{\omega_1}^{\omega_2} \frac{e^{j\omega t}}{(\omega - \omega_0)} \, d\omega \;=\; Re \, \frac{e^{j\omega_0 t}}{2\pi j} \int_{(\omega_1 - \omega_0)t}^{(\omega_2 - \omega_0)t} \frac{e^{ju}}{u} \, du$$
$$= Re \, \frac{e^{j\omega_0 t}}{2\pi} \left\{ \frac{1}{j} \int_{(\omega_1 - \omega_0)t}^{(\omega_2 - \omega_0)t} \frac{\cos u}{u} du \;+\; \int_{(\omega_1 - \omega_0)t}^{(\omega_2 - \omega_0)t} \frac{\sin u}{u} \, du \right\} \qquad (5)$$

Definitions:

$$Si(x) = \int_0^{\infty} \frac{\sin u}{u} \, du, \qquad Ci(x) = -\int_{|x|}^{\infty} \frac{\cos u}{u} \, du \qquad (6)$$

The cos. integral may be split into four integrals:

$$\int_{x_1}^{x_2} \frac{\cos u}{u} du = \overset{(1)}{\int_{x_1}^{|x_1|}} + \overset{(2)}{\int_{|x_1|}^{\infty}} - \overset{(3)}{\int_{x_2}^{|x_2|}} - \overset{(4)}{\int_{|x_2|}^{\infty}} \qquad (7)$$

$$S_i(x) \equiv \int_0^x \frac{\sin z}{x} dx , \qquad C_1(x) \equiv -\int_x^\infty \frac{\cos x}{x} dx$$

$$S_i(x) \simeq \frac{\pi}{2} - \frac{\cos x}{x}$$

$$C_1(x) \simeq \frac{\sin x}{x}$$

<div align="center">SEVENTH LECTURE</div>

If x_1 and x_2 are positive, $x_1 = |x_1|$, $x_2 = |x_2|$, and integrals

(1) and (3) vanish, leaving:

$$\int_{x_1}^{x_2} \frac{\cos u}{u} \, du = C_i(x_2) - C_i(x_1) \tag{8}$$

If $x_1 < 0 < x_2$, we have

$$\int_{x_1}^{x_2} \frac{\cos u}{u} \, du = \int_{x_1}^{|x_1|} \frac{\cos u}{u} \, du + C_i(x_2) - C_i(|x_1|) \tag{9}$$

the integral

$$\int_{-x}^{x} \frac{\cos u}{u} \, du = \int_{-x}^{-\epsilon} + \int_{-\epsilon}^{\epsilon} + \int_{\epsilon}^{x} \quad , \quad \epsilon \to 0 \tag{10}$$

the 1st and 3rd integrals cancel, since $\underline{\frac{\cos u}{u}}$ is an odd

function. We are left with-

$$\int_{-\epsilon}^{\epsilon} \frac{\cos u}{u} \, du = \int_{-\epsilon}^{\epsilon} \frac{du}{u} = \ln \epsilon - \ln(-\epsilon) = \ln\left(\frac{\epsilon}{-\epsilon}\right) = j\pi \tag{11}$$

$$\therefore \int_{x_1}^{x_2} \frac{\cos u}{u} \, du = j\pi + C_i(x_2) - C_i(x_1) \tag{12}$$

If $x_1 < x_2 < 0$, we have

$$\int_{x_1}^{x_2} \frac{\cos u}{u} \, du = j\pi - C_i(|x_1|) - j\pi + C_i(|x_2|) \tag{13}$$
$$= C_i(|x_2|) - C_i(|x_1|)$$

The integral

$$\int_{(\omega_1 - \omega_0)t}^{(\omega_2 - \omega_0)t} \frac{\sin u}{u} \, du = S_i(\omega_2 - \omega_0)t - S_i(\omega_1 - \omega_0)t \tag{14}$$

the total response is then:

$$v_1(t) = Re \; \frac{e^{j\omega_0 t}}{2\pi} \left\{ \left[S_i(\omega_2 - \omega_0)t - S_i(\omega_1 - \omega_0)t \right] + j\left[C_i(\omega_1 - \omega_0)t - C_i(\omega_2 - \omega_0)t \right] \right\}$$

if ω_0 is outside the pass band. If ω_0 is in the band, we have:

$$v_1(t) = Re \; \frac{e^{j\omega_0 t}}{2\pi} \left\{ \left[\pi + S_i(\omega_2 - \omega_0)t - S_i(\omega_1 - \omega_0)t \right] + j\left[C_i(\omega_1 - \omega_0)t - C_i(\omega_2 - \omega_0)t \right] \right\} \quad (16)$$

Paradox: When the impressed frequency is not in the passband, the response ultimately dies out. Then if the impressed frequency is suddenly cut off, the principle of superposition requires that another response of reversed sign shall take place. But the network has physically no driving force at that time, so this response must be a free transient, with modes characteristic of the network alone. How is it then that ω_0 can appear in the solution? In particular, How does the network know what frequency to oscillate at when the drive is removed? How can the network "remember" the frequency ω_0?

EIGHTH LECTURE

Concluding Remarks on Fourier Integrals

Certain general features of Fourier integrals can often
be used to get qualitative answers from physical reasoning without
any equations. Thus, discontinuities in either $f(t)$ or $F(\omega)$
produce wiggles in the other function. This can be seen from the
"Snake in the Complex plane" interpretation of the Fourier integral. $(P.19)$
If the snake is cut off at a certain frequency, the severed end is
rotating at that frequency, and wiggles of that frequency appear
in the time function. This fact may be used in antenna design
where it is desired to eliminate side lobes. In a broadside array,
the angular radiation pattern is the Fourier transform of the ampli-
tude distribution pattern across the array. Since side lobes
represent wiggles on the θ pattern, it is seen that the way to
avoid side lobes is to make the amplitude X distribution fall off
as smoothly as possible, the smoothest way being a Gauss error
curve. The θ pattern is then another Gauss error curve.

The way the frequency function falls off as $\omega \rightarrow \infty$ may be
found by inspection of the function $f(t)$ and the following rules:

If F(t) has a:	F(ω) goes down as:
finite discontinuity	$1/\omega \doteq 6$ db/octave
discontinuity in $\frac{df}{dt}$	$1/\omega^2 \doteq 12$ db/octave
" " $\frac{d^2f}{dt^2}$	$1/\omega^3 \doteq 18$ db/octave
" " $\frac{d^n f}{dt^n}$	$1/\omega^{(n+1)} \doteq 6(n+1)$ db/octave
No discontinuity in any derivative	$e^{-k\omega^2}$
infinite discontinuity (discont. in $\int F dt$)	$F(\omega) \rightarrow$ const.
infinite doublet disc. (discont. in $\iint F dt^2$)	$F(\omega) \rightarrow \omega$
discont. in $\underset{n}{\iint} \cdots F dt^n$	$F(\omega) \rightarrow \omega^{n-1}$

The Reason for this is in the varying quality of cancellation in
the integral defining F(ω), due to the smoothness of F(t). The
smoother this function, the more perfect the cancellation xxxxxxx
will be between adjacent half-cycles of the kernel ~~-jwt~~ $e^{j\omega t}$.

-2-

Analysis of Transmission Lines by the ~~Surface~~ Laplace Transform
Fundamental equations are:

$$v = v(x,t) \quad , \quad i = i(x,t)$$

$$\frac{\partial v}{\partial x} = -\left(Ri + L\frac{\partial i}{\partial t}\right) \quad , \quad \frac{\partial i}{\partial x} = -\left(Gv + C\frac{\partial v}{\partial t}\right). \tag{1}$$

taking the Laplace transforms of these equations:

$$\left(V(x,s) = \int_0^\infty v(x,t)e^{-st}dt \quad , \quad I(x,s) = \int_0^\infty i(x,t)e^{-st}dt\right)$$

we have:

$$\frac{\partial V}{\partial x} = -\left(RI + LsI - Li_0\right) = -(R+Ls)I + Li_0(x)$$

$$\frac{\partial I}{\partial x} = -\left(GV + CsV - Cv_0\right) = -(G+Cs)V + C\dot{v}_0(x) \tag{2}$$

in most practical cases we have $i_0 = 0$, $v_0 = 0$, so we may set up a differential equation for V or I as follows:

$$\frac{\partial^2 V}{\partial x^2} = (R+Ls)(G+Cs)V = \gamma^2 V \quad , \quad \frac{\partial^2 I}{\partial x^2} = \gamma^2 I \tag{3}$$

where

$$\gamma^2 = (R+Ls)(G+Cs) = LC[(s+\rho)^2 - \sigma^2] \tag{4}$$

$$\rho = \frac{1}{2}\left(\frac{R}{L} + \frac{G}{C}\right) \quad , \quad \sigma = \frac{1}{2}\left(\frac{R}{L} - \frac{G}{C}\right)$$

The solution of (3) is obviously

$$V = C_1 e^{\gamma x} + C_2 e^{-\gamma x}$$

$$I = \frac{1}{Z_0}\left[C_1 e^{\gamma x} - C_2 e^{-\gamma x}\right] \tag{5}$$

-3-

where

$$Z_0 \equiv \sqrt{\frac{R+Ls}{G+Cs}}$$

if we have finite initial values, we may put

$$V_0(x) = L\frac{d\,i_0(x)}{dx} - (R+Ls)\,C\,\nu_0(x) \tag{6}$$

and we then add to the solution for V the terms:

$$\frac{e^{\gamma x}}{2\gamma}\int e^{-\gamma x}\,V_0(x)\,dx \;-\; \frac{e^{-\gamma x}}{2\gamma}\int e^{\gamma x}\,\nu_0(x)\,dx \tag{7}$$

Equations (5) are recognized as traveling waves, and their similarity with the well-known, steady-state equations suggests that we can simply use the steady-state equations in all manipulations, and then take the inverse transform of the result to get our transient solution.

NINTH LECTURE

Example: Distortion of a Unit Step After Traveling thru a
Length of Transmission Line.

Initial voltage $= v(o,t) = u(t)$

voltage at point $x = v(x,t)$

Transform of initial voltage $= \cancel{V(o,s) = \frac{1}{s}}$ $V(o,s) = \frac{1}{s}$

transform at point x is $\cancel{V(x,s) = V(o,s)e^{-\gamma x} = \frac{1}{s} e^{-\gamma x}}$ $V(x,s) = V(o,s)e^{-\gamma x} = \frac{1}{s} e^{-\gamma}$

$$\gamma = \frac{1}{v_o} \sqrt{(s+\rho)^2 - \sigma^2}$$

where $v_o = \frac{1}{\sqrt{LC}}$

$\rho = \frac{1}{2}\left(\frac{R}{L} + \frac{G}{C}\right)$ attenuation constant

$\sigma = \frac{1}{2}\left(\frac{R}{L} - \frac{G}{C}\right)$ distortion constant

$$\therefore \quad V(x,s) = \frac{1}{s} e^{-\frac{x}{v_o} \sqrt{(s+\rho)^2 - \sigma^2}}$$

Pair 863.1 of C.F. is

$$e^{-y\sqrt{(s+r)(s+\rho)}} \quad - e^{-y\left[s + \frac{1}{2}(r+\rho)\right]}$$

$$\longrightarrow \frac{y(r-\rho)}{2\sqrt{t^2-y^2}} \; e^{-\frac{1}{2}(r+\rho)t} \quad I_1\left[\frac{1}{2}(r-\rho)\sqrt{t^2-y^2}\right] \qquad (y < t)$$

We identify $(s+r)(s+\rho) = (s+\rho)^2 - \sigma^2$

$\frac{1}{2}(r+\rho) = \rho$

$\frac{1}{2}(r-\rho) = \sigma$

$y = \frac{x}{v_o} = t_o$

so the pair becomes:

$$e^{-t_0 \sqrt{(s+\rho)^2 - \sigma^2}} - e^{-(s+\rho)t_0} \rightarrow \frac{\sigma t_0}{\sqrt{t^2 - t_0^2}} e^{-\rho t} I_1 \left[\sigma \sqrt{t^2 - t_0^2} \right] \qquad (t_0 < t)$$

the quantity $e^{-(s+\rho)}$ to has the inverse transform $e^{-\rho t_0} u_{-1}(t - t_0)$

a "unit impulse" at t = to with area $e^{-\rho t_0}$, so we have:

$$e^{-t_0 \sqrt{(s+\rho)^2 - \sigma^2}} \longrightarrow \frac{\sigma t_0}{\sqrt{t^2 - t_0^2}} e^{-\rho t} I_1 \left[\sigma \sqrt{t^2 - t_0^2} \right] + e^{-\rho t_0} u_{-1}(t - t_0)$$

This is the same as $V(x,s)$ except for a factor 1/S which denotes

integration with respect to t.

Therefore, we have:

$$v(x,t) = \frac{\sigma x}{v_0} \int_{t_0}^{t} \frac{e^{-\rho t}}{\sqrt{t^2 - t_0^2}} I_1 \left[\sigma \sqrt{t^2 - t_0^2} \right] dt + e^{-\rho t_0} u(t - t_0)$$

This is a unit step of height $e^{-\rho t_0}$ at t = to, plus

distortion terms due to the integral. The modified Bessel

Function I_1 bears somewhat the same relation to an ordinary

Bessel Function Jn(Z) as hyperbolic functions do to trigonometric

ones. Thus:

$$I_n(z) = i^{-n} J_n(z i) \qquad \left(i = \sqrt{-1} \right)$$

which corresponds to

$$\sinh(z) = i^{-1} \sin(z i)$$

this analogy can be seen also from the equations

$$J_{\frac{1}{2}}(z) = \sqrt{\frac{2}{\pi z}} \sin z$$

$$I_{\frac{1}{2}}(z) = \sqrt{\frac{2}{\pi z}} \sinh z$$

Infinite series for In(Z) is:

$$I_n(z) = \left(\frac{z}{2} \right)^n \sum_{m=0}^{\infty} \frac{\left(\frac{z}{2} \right)^{2m}}{m! (n+m)!}$$

the series for $J_n(\mathbf{z})$ is the same except that signs alternate $+$ and $-$, again corresponding to the relation between hyperbolic and trigonometric functions. Using the infinite series representation for $I_1(\mathbf{z})$, we have

$$v(x,t) = \frac{\sigma t_0}{2} \int_{t_0}^{t} e^{-\rho t} dt \sum_{m=0}^{\infty} \frac{\left[\frac{\sigma}{2}\sqrt{t^2-t_0^2}\right]^{2m}}{m!(n+m)!} + e^{-\rho t_0} u(t-t_0)$$

$$= \frac{\sigma t_0}{2} \sum_{m=0}^{\infty} \frac{\left(\frac{\sigma}{2}\right)^{2m}}{m!(n+m)!} \int_{t_0}^{t} e^{-\rho t}\left[t^2-t_0^2\right]^{m} dt + e^{-\rho t_0} u(t-t_0)$$

The result is expressed as an infinite series. The accuracy attained depends on the number of terms carried. If we carry the first two, with m=0 and m= 1, the result will be valid for $\sigma\sqrt{t^2-t_0^2} < 1$.

If $m = 0$, we have

$$\int_{t_0}^{t} e^{-\rho t} dt = \frac{1}{\rho}\left[e^{-\rho t_0} - e^{-\rho t}\right]$$

when $m = 1$,

$$\int_{t_0}^{t} e^{-\rho t}\left[t^2-t_0^2\right] dt = -\frac{e^{-\rho t}}{\rho}\left[t^2 + 2\frac{t}{\rho} + \frac{2}{\rho^2}\right]$$

$$+ \frac{e^{-\rho t_0}}{\rho}\left[t_0^2 + 2\frac{t_0}{\rho} + \frac{2}{\rho^2}\right] + \frac{t_0^2}{\rho}\left[e^{-\rho t} - e^{-\rho t_0}\right]$$

For the voltage $v(x,t)$ we then have, to this approximation:

$$v(x,t) = \frac{\sigma t_0}{2\rho}\left\{\left(1 - \frac{\sigma^2 t_0^2}{8}\right)\left(e^{-\rho t_0} - e^{-\rho t}\right)\right.$$

$$+ \frac{\sigma^2}{8}\left[e^{-\rho t_0}\left(t_0^2 + 2\frac{t_0}{\rho} + \frac{2}{\rho^2}\right) - e^{-\rho t}\left(t^2 + 2\frac{t}{\rho} + \frac{2}{\rho^2}\right)\right]\right\}$$

$$+ e^{-\rho t_0} u(t-t_0)$$

The final value at $t \to \infty$ may be found from the following theorem :

$$f(\infty) = \lim_{s \to 0} \; s \; F(s) = e^{- x \sqrt{RG}}$$

so that the final distribution is a steady voltage, decreasing exponentially with distance from the generator.

The pulse shape taking only the 1st term of the infinite series is given by:

$$v(x,t) = \frac{\sigma^2 t_0}{2\rho} \left[e^{-\rho t_0} - e^{-\rho t} \right] + e^{-\rho t_0} u(t - t_0)$$

This predicts a final value of

$$e^{-\rho t_0} \left[1 + \frac{\sigma^2 t_0}{2\rho} \right]$$

whereas the exact value has been found equal to:

$$e^{- x \sqrt{RG}} = e^{- t_0 \sqrt{\rho^2 - \sigma^2}} = e^{-\rho t_0 \sqrt{1 - (\frac{\sigma}{\rho})^2}}$$

This may be approximated by:

$$e^{-\rho t_0 \sqrt{1 - (\sigma/\rho)^2}} \cong e^{-\rho t_0 [1 - \sigma^2/2\rho^2]} = e^{-\rho t_0} e^{\frac{\sigma^2 t_0}{2\rho}}$$

$$\cong e^{-\rho t_0} \left[1 + \frac{\sigma^2 t_0}{2\rho} \right]$$

This is identical with the value given by the first term of the series, showing that the approximate solution is quite good, even for large t. Incidentally, the equations show that the percentage of distortion terms increases as we go down the line, so that eventually

the initial sharp rise is lost in distortion terms. The final

value is always greater than the value of the initial sharp jump.
